What are voids?

- Large 3D regions
- 50% of volume
- < 20% of galaxies

Why are we interested in them?

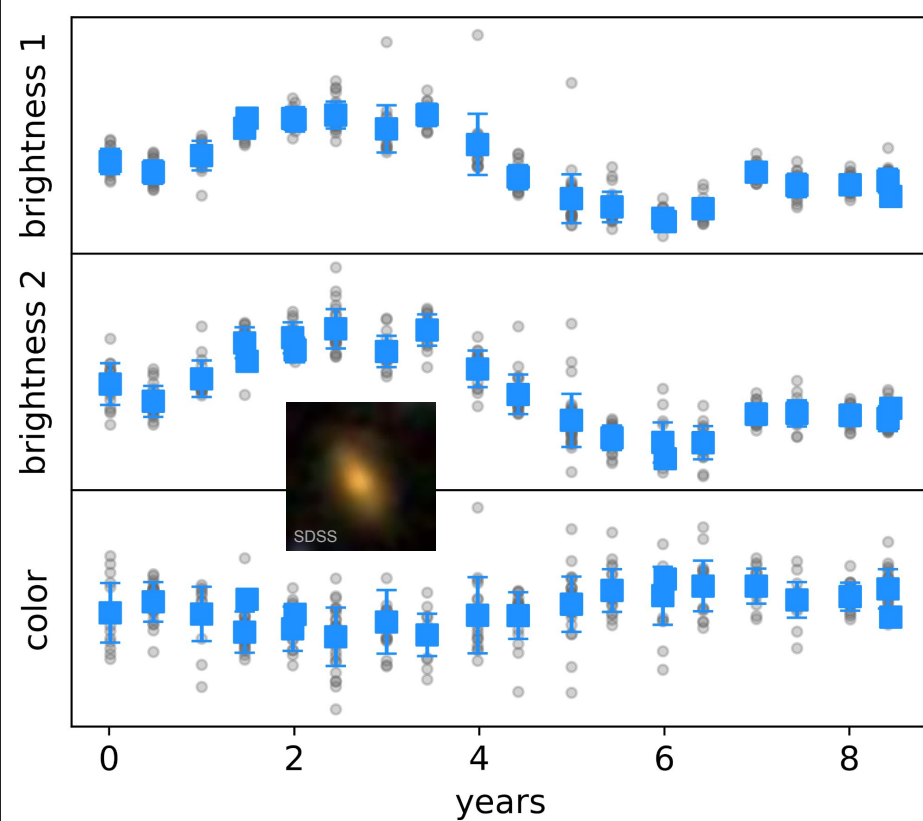

- Mergers → “hungry” monster black holes (BHs)?
- Harder to find active BHs

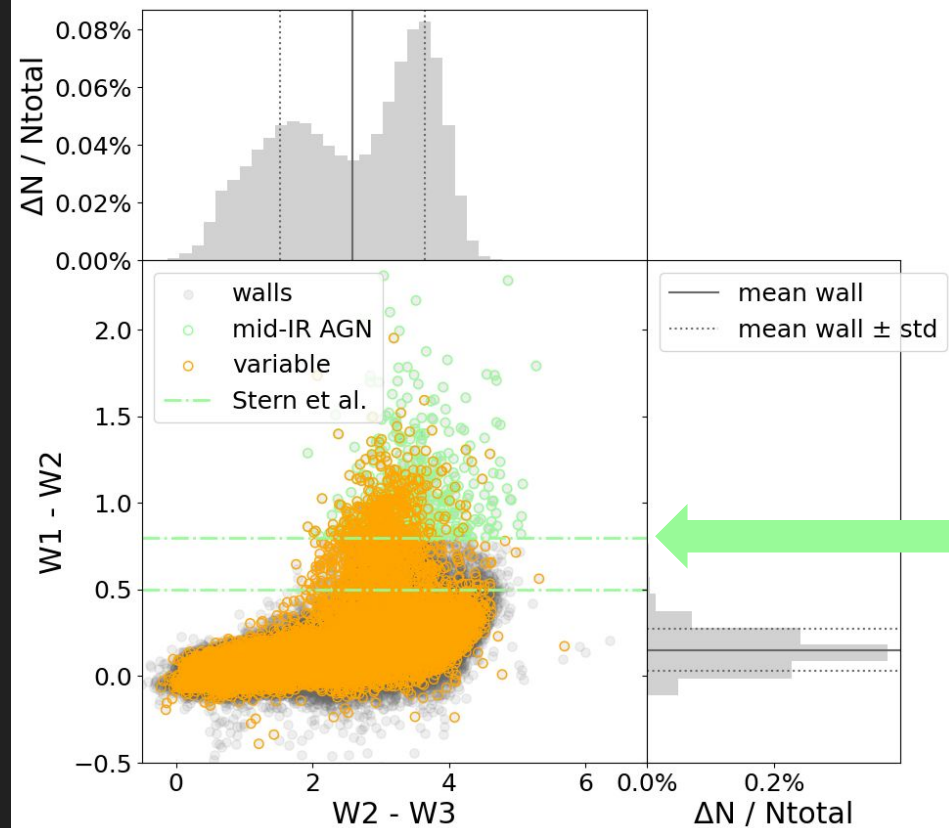

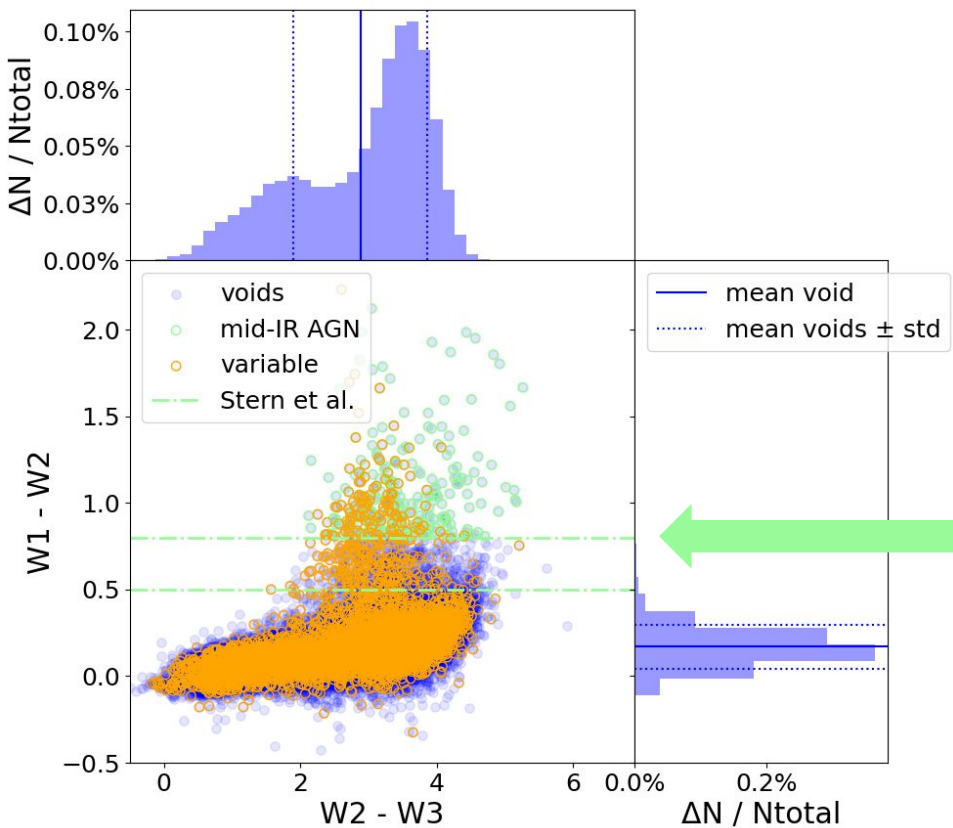

Variability uncovers hidden hunger

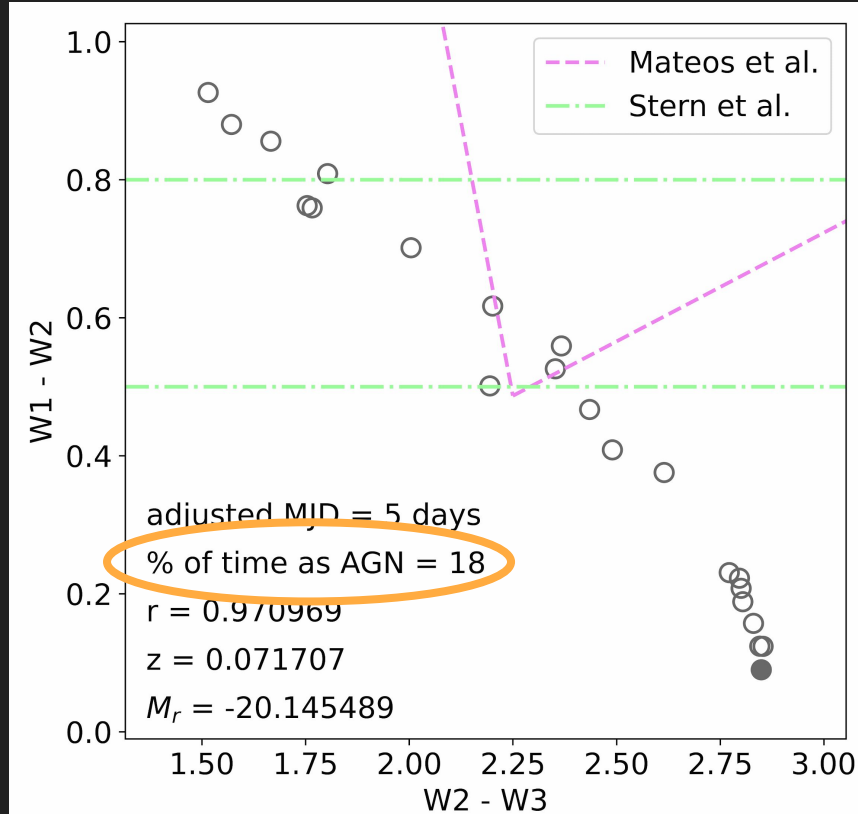

Mid-infrared (mid-IR) data
(AllWISE/NEOWISE)

> 20,000 “hungry” monster
BHs in overlooked “blue”
galaxies (~ 7%)

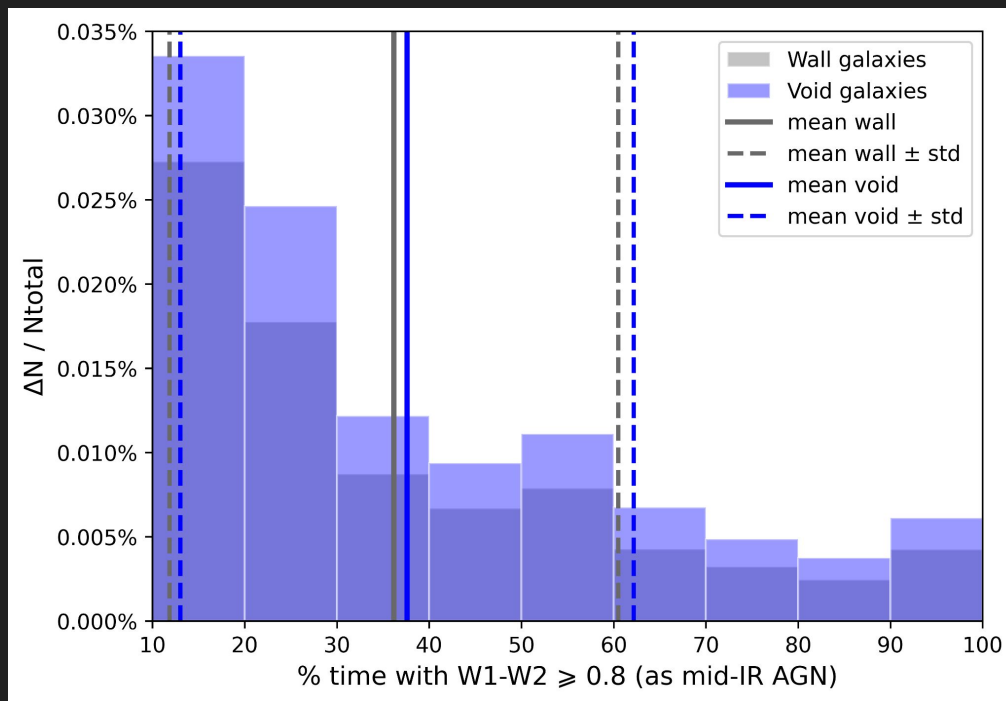

Changing BHs evade traditional methods

Lonely BHs may also be the hungriest

Hungry BHs are **more common in voids** among midsize/dwarf galaxies

Reverse trend when comparing **all** galaxies

Shedding light on galaxy evolution

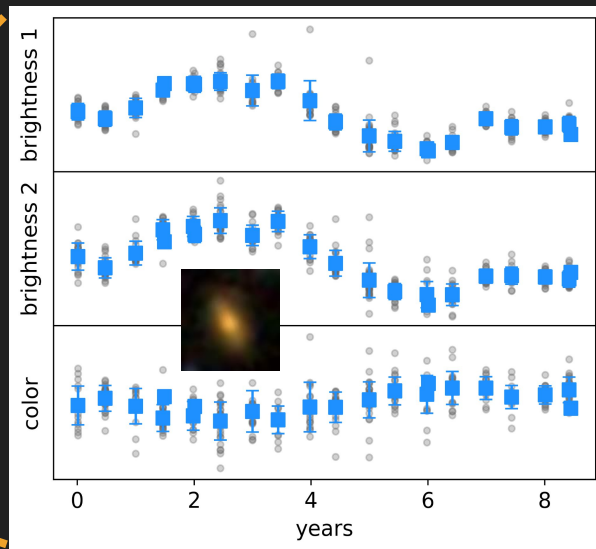

Interactions encourage
“snacking” only among more
luminous galaxies

Monster BH life cycle is
delayed/slowed in voids
