Evidence for a Dominant Formation Channel for FRBs

Mohit Bhardwaj

McWilliams Fellow, Carnegie Mellon University Aaron Pearlman Banting Fellow, McGill University & Trottier Space Institute

On behalf of the CHIME/FRB collaboration

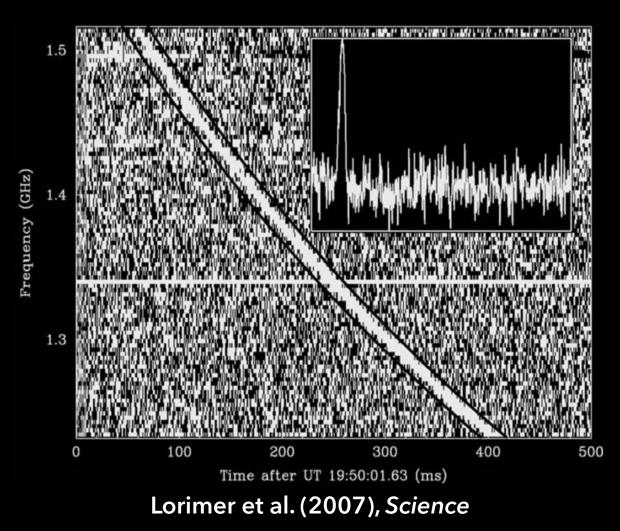

What are FRBs?

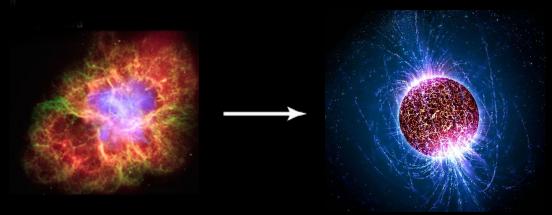

Bright radio pulses of millisecond duration

Origins unknown, but some likely produced by magnetars

Intervening material distorts radio signal due to dispersion

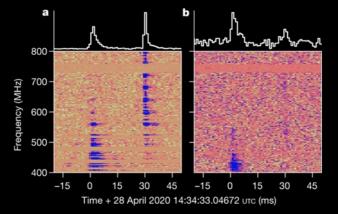

Multiple Formation Channels?

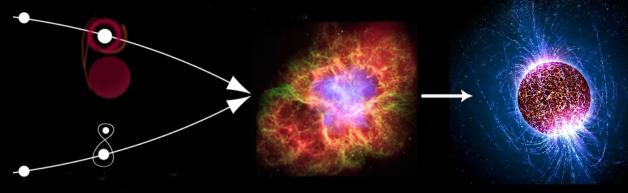

Young Progenitor Scenario

FRB-like radio bursts from SGR 1935+2154

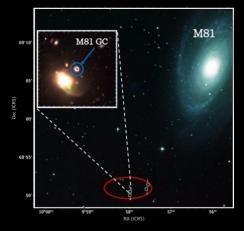

CHIME/FRB Collaboration et al. (2020), *Nature* Bochenek et al. (2020), *Nature*

Old Progenitor Scenario

FRB located in a globular cluster of M81

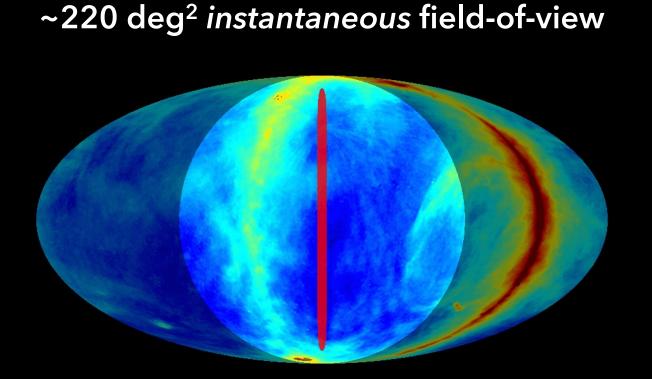

Bhardwaj et. al (2021a), ApJL Kristen et al. (2022), *Nature*

CHIME/FRB is detecting 100 FRBs / month

CHIME/FRB Project: Collaboration of ~80 Scientists

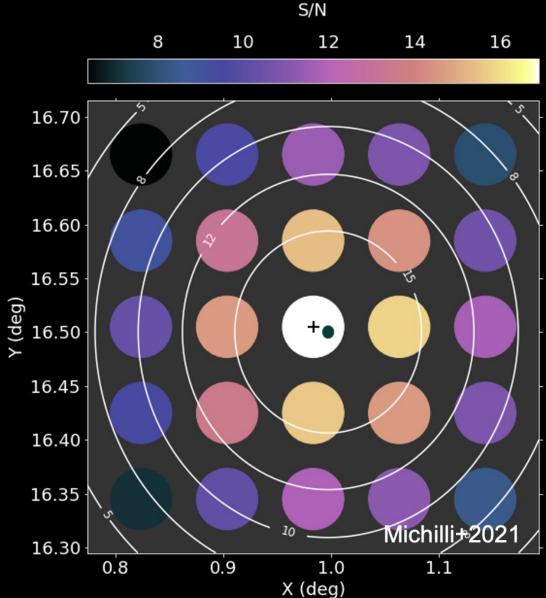

CHIME: Radio telescope located in Penticton, Canada Searching for FRBs in real-time

Pinpointing the Source Position

Host galaxies of nearby FRBs can be identified by combining voltage data from all antennas

Typical Localization Precision: ~1 arcmin

Local Universe FRB Hosts (z<0.1)

18 local Universe FRBs with robust host association published till July 2023.

Over 50% were discovered by CHIME/FRB (highlighted in red boxes)

All are late-type (spiral) galaxies!

Core-collapse Supernovae as Dominant Formation Channel

Direct collapse of massive stars to form FRB sources

Summary

Local Universe FRBs are the very promising candidates to uncover the origins of FRBs.

We have associated four CHIME FRBs to nearby spiral galaxies.

Prevalence of spiral hosts in the local Universe FRB sample.

Core-collapse supernovae are likely the dominant FRB formation channel.

We need more FRB host localizations to confirm our finding and identify other (subdominant) formation channels.

We will soon localize 100s of FRBs every year using the upcoming CHIME/FRB Outrigger telescopes.

FRBs have a bright future!
