

Close Encounters of the Supermassive Black Hole Kind

Tidal Disruption Events and what they can reveal about Black Holes and Stars in Distant Galaxies

Ananya Bandopadhyay^{1*}, Julia Fancher¹, Aluel Athian², Valentino Indelicato², Sarah Kapalanga², Angela Kumah², Daniel A. Paradiso¹, Matthew Todd¹, Eric R. Coughlin¹, and C. J. Nixon³, *The Astrophysical Journal Letters* (2024).

TDE observations so far

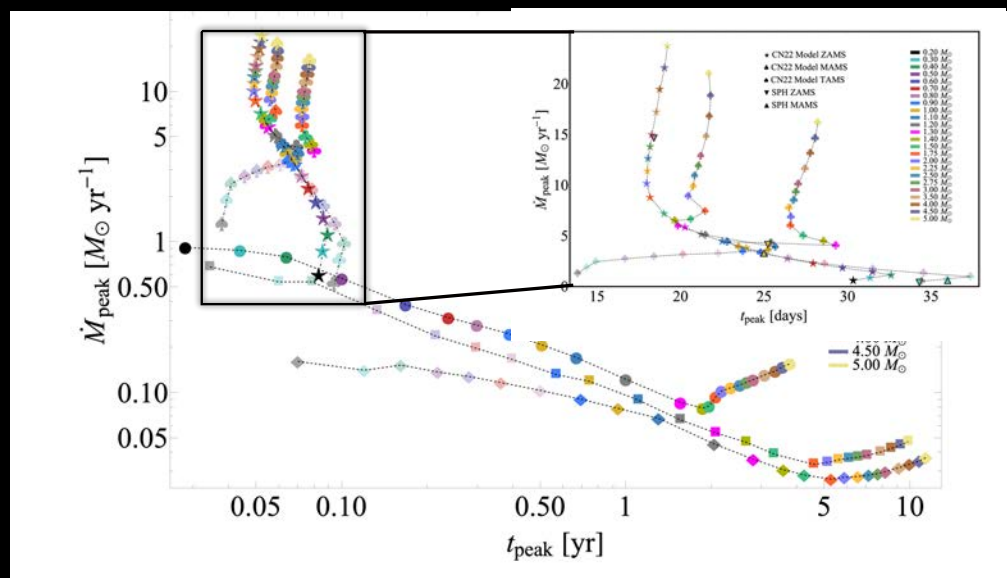

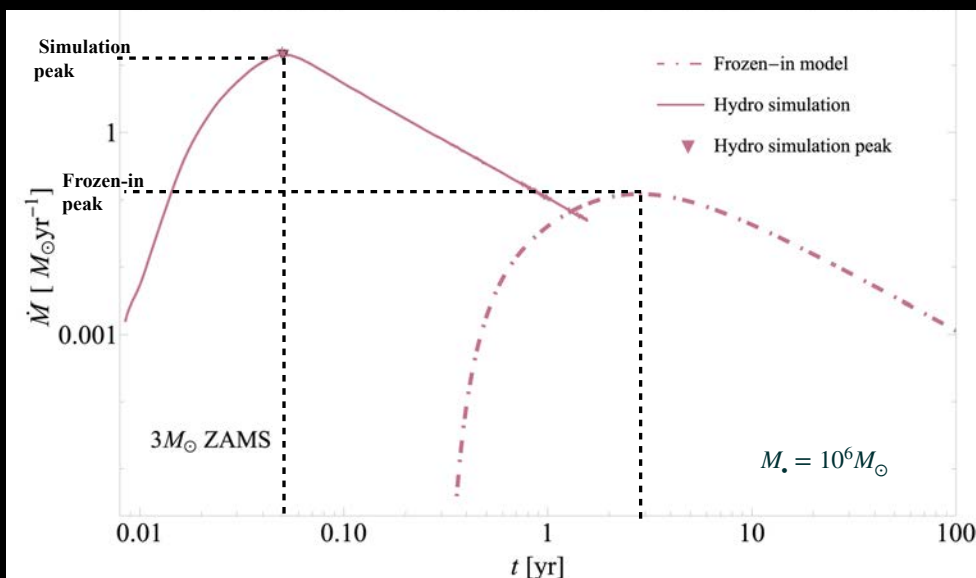

~100 TDEs observed so far at multiple wavelengths from radio to X-ray, by wide-field surveys such as the ZTF, ASAS-SN, eROSITA.

What determines the peak of the light curve and the peak timescale?

Image credit: Hammerstein, E., et al. *ApJ*, 942, 9 (2023).

Peak Fallback Rate of Stellar Debris

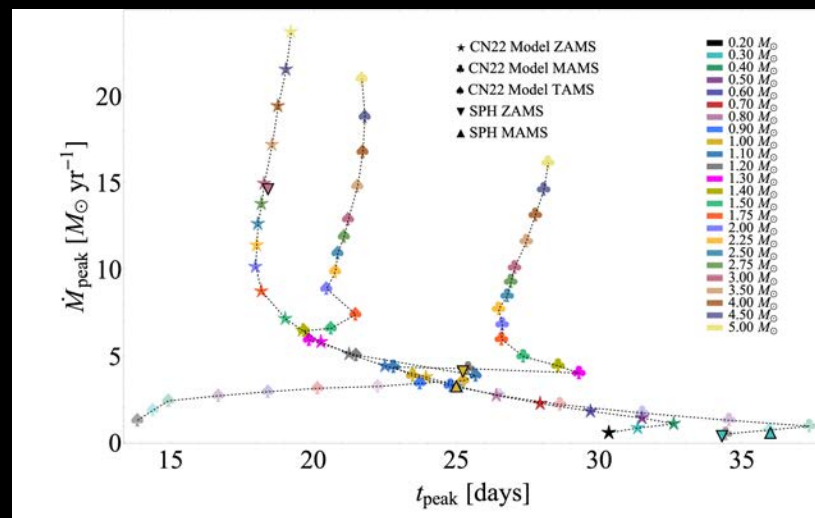

Comparison of peak fallback rate and time of peak for the “frozen-in” model, and the analytical model developed by Coughlin&Nixon (2022)*.

$$t_{\text{peak}} \approx 30 \times (M_*/10^6 M_\odot)^{1/2} \text{ days}.$$

*Coughlin and Nixon, MNRAS **517**, L26(2022).

Implications — jetted TDEs

- Highly super Eddington accretion rates are likely required for the launching of relativistic jets from TDEs.
- Such high accretion rates arise from the disruption of high mass stars.
- The rarity of occurrence of high mass stars could provide a possible explanation for the rarity of observation of jetted TDEs.
- Young star-forming galaxies likely to be host galaxies for jetted TDEs.

Poster session from the **Syracuse University Research in Physics (SURPh)** summer research program, involving high school students from the **Syracuse City School District (SCSD)**. They used computational tools and performed numerical simulations to test the CN22 model, serving as co-authors for the study.
